TITIE: Change in throughput capacity of the spinal column efferent outlet in tetanus intoxication

SOURCE: Byulleten' eksperimental'noy biologii i meditsiny, v. 58. no. 9, 1964, 12-17

TOPIC TAGS: medical experiment, experiment animal, brain, nervous system, neuron, toxicology, neurology

ABSTRACT: Results of experiments on cats with high section of the spinal cord (C7-Th1) 2 to 6 days after introduction of tetanus toxin into the calf muscle are presented. Throughout capacity of the efferent outlet of the spinal cord rose on the injection side and was expressed by an increase of monosynaptic reflex reproduction in the course of rhythmic stimulation of muscular afferents. High-frequency reproduction of monosynaptic reflexes is especially enhanced in combined mono- and polysynaptic stimulation. Under these conditions, monosynaptic reflexes may be reproduced with 100, 200, and even 300 stimuli per second. The two mechanisms responsible for the observed phenomena are: disturbance of the various types of

Card 1/2

L 1592-66

postsynaptic inhibition of the motor neurons, and their additional polysynaptic activation. The latter is markedly intensified in tetanus intoxication. The discussion covers the significance of each of the mechanisms and some aspects of control of the throughput capacity of the spinal cord efferent output. Orig. art. has: 3 figures.

	†
SOURCE: Metallurg, no. 3, 1966, 27-28	!
TOPIC TAGS: low carbon steel, deoxidation, cold rolling, quality control / 08)	u steel
ABSTRACT: Production testing was carried out on nonaging 08Yu steel sheets at Cherepovetsky Metallurgical Plant and the results were compared to the norms see GOST 9045-59. Melting was carried out in single-grooved Martens furnaces of averagacity; deoxidation by ferromanganese was done in steps50% in the furnace as in the ladle; Al was also introduced in the ladle in quantities of 160-150 g/T steel while full deoxidation was accomplished by the addition of Al pellets in ties of 900-1000 g/T. The chemical composition of 08Yu steel compared favorable the standards set by GOST 9045-59 (experimentallyC=0.04-0.08%, Si=0.01%, Mn=0-0.38%, S=0.009-0.016%, P=0.01-0.015%, Cr=0.01-0.03%, Ni=0.03-0.07%, Cu=0.02-0.Al=0.02-0.05%). Ingots weighing 14T were hot rolled in 15-18 passes into slabs	et by verage and 50% of quanti- y with

135-140 mm thickness and 1070-1430 mm width on a 1150 bloom. These slabs were next cold rolled to a maximum of 68% reduction into sheets of 2.5-3.5 mm thickness and 1040--1430 mm width. \Annealing was done at 550°C for 10 hrs at a heating rate of 15°/hr and cooling was at 60/hr. The final operation was a finishing pass at 1.0-1.3% reduction. Tests made on the sheets after aging at 200°C for 30 min substantiated that the steel was nonaging. The sheets performed well in stamping tests which were run under the stamping conditions used at the Gor'ky Automotive Plant. Orig. art. has: 1

Spraying experiments against gooseberry powdery mildew [Sphaerotheca morsuum: see preceding and next abstracts] were carried out in the U.S.S.R. in 1951. Copper sprays (4 per cent.) on dormant bushes and the soil beneath immediately after the snow-thaw, with applications of manure [R.A.M., 31, p. 129], further sprays before the infection appears or soon after, and then every 10 to 12 days in warm, rainy weather or 20 to 25 days in colder, dry weather until infection disappears completely, give satisfactory control. Where infection is severe the burning of infected herries and leaves and the removal of suckers are recommended.

p 91 (USSR)

AUTHOR: D'yakonova-Savel'yeva, Ye. N.

TITLE: Variegated Formation of Eastern Crimea (Pestrotsvetnaya

tolshcha vostochnogo Kryma)

PERIODICAL: Tr. Leningr. o-va yestestvoispyt., 1957, Vol 69, Nr 2,

pp '68-80

ABSTRACT: The author describes a small series of variegated

volcanic rocks which can be seen outcropping in separate places between the Kiik Altam Cape and the Kara Dag Massif (the latter appears to be the analogue of this formation in age and origin). Full section of the variegated formation was studied in the eastern part of the Yanisharskaya burkhta (Bay). At the base of the formation lie argillaceous slates with marls, which the

author refers to the Bajocian. (In the summer of 1956

these deposits produced the imprints of Monotis caucasica Witt., which placed them in the Upper

15-57-12-17295

Variegated Formation of Eastern Crimea (Cont.)

Above the slates lies a sequence of numerous Triassic. (Editor)7. tuffaceous sandstones (22 m) from which Parkinsonia parkinsoni Sow., Posidonia buchi Roem., and other forms have been gathered; these determined the age of these sandstones as Bajocian. Above these lie loose, brown fragmental tuffaceous deposits (12 m) which are covered by a layer (22 m) of a similar composition, but containing continuous interlayers. Farther up follow the layers (31 m) of coarsely fragmental andesite breccia (5 m) which is characterized by its pyrite-bearing lava cement. This is followed by the sandstones alternating with argillaceous shales (14 m), by dacitic lava and by clay formations of jasper-like color (10 m). These sandstones are overlain by Bathian clays. The formation is not extensive laterally. As it approaches the Kara Dag, its andesite-dacite lava sheets of cenotypal appearance become ever more dominant. The author investigates in detail the structure of the Kara Dag Massif as well as the conditions under which the Kara Dag lavas and variegated rocks were formed. The greater part of the layers are gray, brown or green, the color depending on the pigmentation of the mineral and rock fragments or of the cement. The volcanic products are chemically related to Card 2/4

15-57-12-17295

Variegated Formation of Eastern Crimea (Cont.)

the varieties of andesi'tic and dacitic mugma. The variegated formation is associated with the zones of underwater extrusions which originated in the same epoch as the Kara Dag group (Bajocian-Bathian). The period of its formation corresponds to the first stage of extrusion in the cenotype cycle. The formation of dacite and ande ite sheets and of necks and dikes which intersect the old stratified series occurred in the second stage of the same cycle. After a period of rest of volcunic activity, which corresponds to the deposition of the Bathian clay, there followed an outpouring of pale-oliparites which in turn were followed by the outpourings of Lower Callovian. The outpourings and the extrusions of the volcanic products which formed the variegated formation and the whole cenotype series of the Kara Dag are associated with a center of basic magma, which was located to the east from the center of origin of the basic sodium magma which has produced the old series (western part of the Kara Dag Massif). The variegated formation of eastern Crimea represents a typical geosynclinal formation of the Middle Jurassic. It exhibits no features found in the deposits of the fore-mountain Card 3/4

15-57-12-17295

USSR/Medicine - Post-Transfusion Hepatitis Dec 53

"The Prophylaxis of Post-Transfusion Virus Hepatitis," Prof S. I. Sherman, S. I. Diakonovich, I. A. Yurikas, A. V. Blinova, A. V. Alekseyeva, R. S. Germant, Leningrad Sci-Res Inst of Blood Transfn; Div of Virol, Inst Exptl Med, Acad Med Sci USSR, Len-Ingrad

Klin Med, Vol 31, No 12, pp 57-61

Describes results of lab work on post-transfusion hepatitis conducted in 1946-1952. States that lab findings revealed the superiority of the qualitative billrubin blood test (direct reaction) over the

quantitative test in the detn of a pre-jaundice or post-jaundice condition in blood lonors.

MILLY HOLDINGAICH 21 Country : USSR Category : Human and Animal Physiology, Blood \mathbf{T} Abs. Jour. : Ref Zhur - Biol., No. 2, 1959, No. 7948 Author : Rafal'son D.; Ashkinazi L.; Diakanovich S. Instabut. Titl: : The Role of the Central Nervous System in the Mechanism of Blood Regeneration in Donors. Orig Pub. : V sb.: Aktual'n. vopr. pereliv. krovi. Vyp. 5, Leningrad, 1957, 14--21 lbatrict : The study was performed on 175 donors between the ages of 21 and 50 who had been donors for at least 3 years. Normal regeneration of blood was observed in 100 donors after they had given blood; in 75, regeneration was diminished. According to type of higher nervous activity, the donors were designated as strong, weak and intermediate. Bromine and strychnine were used to alter the reaction of the organism to giving blood. When Br was given (30 ml of a 3% solution 1 hour before blood was taken), in those donors with reduced blood regeneration the fall

Country : USSR Cutogory: : Human and Animal Physiology, Blood Abs. Jour. : Ref Zhur - Biol., No. 2, 1959, No. 7948 nuthor Institut. Title Orig. Pub. : : in Hb, eythrocyte and reticulocyte levels Abstract immediately after 280 ml of blood was taken and five days later was negligible in comparison with that seen in the donors which did not receive Br. The same result was observed in donors with normal and retarded regeneration after 400 ml of blood was taken. Donors with retarded blood regeneration which did not receive Br showed a sudden drop in red blood indices after losing 280 ml of blood. Strychnine exerted a regulatory effect on donors Card: 2/4

: with reduced regeneration (10) in the sense of equalizing the red cell indices following the loss of blood. A diminished regenerative capacity was observed most often in the weak type of donor. Blood regeneration in donors after giving blood is accomplished in the presence of the regulatory influence of the central nervous system. Pharmacological agents can to a certain extent affect the reaction of the donor's blood following blood loss and the time required for replacement of the blood. When the regenerative capacity of the blood is

PERIODICAL:

Gornyy zhurnal, 1958, Nr 10, pp 29-31 (USSR)

ABSTRACT:

when pits 55 and 57 of the Dzhezkazgan Copper Mine were sunk, their vertical shafts were strengthened with concrete without installing supporting rims. The concrete was poured into the portable metallic molds installed in the pits which were then gradually lowered in pace with the sinking of the shaft. In such a way, temporary strengthening was not needed and the whole operation made a considerable saving of money and labor. In 6 months, 278 m of both shafts were strengthened without the supporting rims. The cost of 1 m of shaft was 1,030 rubles less, the speed of sinking increased by 11% and the working productivity by 6%. There is 1 diagram and 1 Soviet reference.

Intensities of Auger K-electron groups of rare-earth

elements

PERIODICAL:

Akademiya nauk SSSR. Izvestiya. Seriya fizicheskaya, v. 26,

no. 2, 1962, 191-196

TEXT: The energy of Auger electrons was measured with a magnetic-lens beta-ray spectrometer of the Kafedra yadernoy spektroskopii LGU (Department of Nuclear Spectroscopy of LGU). The electrons were accelerated with an electric field on the section of the flight-path section parallel to the axis of the apparatus between two lenses. The counter, filled with argon and alcohol vapor (ratio 1:1, pressure 26 mm Hg), was sealed by a collodion film with a transmission threshold of 3-4 kev. Electrons of more than 27 kev were completely transmitted. The apparatus was calibrated by the

A- and F-lines of ThB and the L 58-line of Dy 159 . The relative half-width of these lines was 2.0 %. Samples were obtained by chromatographic separation of the rare earths from a tantalum target which was bombarded

TITLE:

Petroleum and Gas Prospects of Western Kazakhstan and

Principal Trends of Regional Exploration and Prospecting

PERIODICAL: Geologiya nefti i gaza, 1960, No. 2, pp. 10 - 15

TEXT: In accordance with the resolutions of the XXI Party Congress of the CPSU, the petroleum industry in Kazakhstan was assigned the task of producing large industrial petroleum and gas stocks within the Seven-year Plan. Western Kazakhstan includes the Caspian depression with one of the largest salt domes in the world. Prospecting for petroleum and gas in this territory is to be carried out in four directions corresponding to geological formations: 1) in the complex of salt domes above the salt layer; 2) in the Paleozoic zone beneath the salt layer; 3) in the Mesozoic zone of North Ustyurt and the Buzachi peninsula; and 4) in the Mesozoic zone

of South Mangyshlak and South Ustyurt. Two million meters of deep drilling will be necessary. The most promising directions and regions for the exploration are now being determined. These are: 1) the Mesozoic structures and the sea bottom at Karaton; 2) the region north of Dossor-Makat where high-quality fatty oil is suspected; 3) the north-eastern part of the Caspian depression in the direction from Makat toward Shuburkuduk; and 4) the region between Volga and Ural where abundant natural escape of gas has already been attracting the attention of geologists for a long time. Of the other regions, South Mangyshlak and South Ustyurt are the most promising petroleum deposits. In the time of the Seven-year Plan a number of scientific explorations are planned in Western Kazakhstan, geological surveying of the entire territory of Ustyurt and most of the Caspian depression on a scale 1: 200 000, seismic exploration, trial drilling and electroexploratory work according to the telluric current method with which the presence of tectonic elements of first and second order has been established. For the exploration of Paleozoic deposits in the central part of the Caspian depression 10 drillings are planned, one of them to be to
